“A software product line (SPL) is a set of software-intensive systems that **share a common, managed set of features** satisfying the specific needs of a particular market segment or mission and that are **developed from a common set of core assets** in a prescribed way.”

# Advantages of SPLs

- Tailor-made software
- Reduced cost
- Improved quality
- Reduced time to market

SPLs are ubiquitous

# Challenges of SPLs

- Upfront cost for preparing reusable parts
- Deciding which products you can produce early on
- Thinking about multiple products at the same time
- Managing/testing/analyzing multiple products

# Feature-oriented SPLs

---

Thinking of your product line in terms of the **features** offered.

# Examples of a Feature (Graph Product Line)

feature:  
edge color

feature:  
edge type  
(directed vs. undirected)

feature:  
cycle detection

# Examples of a Feature

(*Collections* Product Line)

- Serializable
- Cloneable
- Growable/Shrinkable/Subtractable/Clearable
- Traversable/Iterable
- Supports parallel processing

# Feature

---

A **feature** is a *characteristic or end-user-visible behavior of a software system*. Features are used in product-line engineering to specify and communicate *commonalities* and *differences* of the products between stakeholders, and to guide structure, reuse, and variation across all phases of the software life cycle.

# What features would a Smartphone SPL contain?

Discussion

# Feature Dependencies

---

Constraints on the possible feature selections!

feature:  
edge type  
(directed)

*depends on*

feature:  
cycle detection

# Product

---

A **product** of a product line is specified by a *valid feature selection* (a subset of the features of the product line). A feature selection is valid if and only if it fulfills all feature dependencies.

# Valid Products

## Feature Dependencies

## Product Configurations

	Edge Color	Directed Edge	Cycle Detection
Product 1	✓	✓	✓
Product 2	✓		✓

# Domain Implementation

Domain Implementation

- Underlying code must be variable
- Dimensions of implementation techniques
  - Binding times: compile-time binding, load-time binding and run-time binding.
  - Representation: annotation vs composition

# Domain Implementation (Representation)

Domain Implementation

Annotation-based Approach

Composition-based Approach

# Variability Implementation

Domain Implementation

- Parameters
- Design patterns
- Build systems
- Preprocessors
- *Feature-oriented programming*

# Variability Implementation Parameters

- ★ simple
- ★ flexible
- ★ language support
- code bloat
- computing overhead
- non-modular solution

# Variability Implementation Design Patterns

Domain Implementation

- ★ well established
- ★ easy to communicate design decisions
- architecture overhead
- need to preplan extensions

# Variability Implementation Build Systems

- ★ simple if features can be mapped into files
- ★ can control other types of parameters
- code duplication if finer level of granularity needed
- hard to analyze

# Variability Implementation Preprocessors

- ★ Easy to use, well-known
- ★ Compile-time customization removes unnecessary code
- ★ Supports arbitrary levels of granularity
- No separation of concerns (lots of scattering & tangling)
- Can be used in an undisciplined fashion
- Prone to simple (syntactic) errors

# Variability Implementation Feature-Oriented Programming

- ★ easy-to-use language mechanism, requiring minimal language extensions
- ★ compile-time customization of source code
- ★ direct feature traceability from a feature to its implementation
- requires composition tools
- granularity at level of methods
- *only academic tools so far, little experience in practice*

# Research Topics

- feature-model reengineering/extraction from existing code
- detecting inconsistencies between the feature-model and its “implementation”
- feature interactions - intended vs. unintended?

# A Software Product Line for Static Analyses

## The OPAL Framework

Michael Eichberg Ben Hermann

Technische Universität Darmstadt  
{lastname}@cs.tu-darmstadt.de

### Abstract

Implementations of static analyses are usually tailored toward a single goal to be efficient, hampering reusability and adaptability of the components of an analysis. To solve these issues, we propose to implement static analyses as highly-configurable software product lines (SPLs). Furthermore, we also discuss an implementation of an SPL for static analyses – called OPAL – that uses advanced language features offered by the Scala programming language to get an easily adaptable and (type-)safe software product line.

OPAL is a general purpose library for static analysis of Java Bytecode that is already successfully used. We present OPAL and show how a design based on software product line engineering benefits the implementation of static analyses with the framework.

### 1. Introduction

When designing static analyses we aim for efficiency and scalability so that the analyses can tackle reasonable and therefore interesting problems. In order to achieve these design goals static analyses are usually tailored toward solving a single, specific set of problems and therefore often lack generality and reusability. In order to foster reusability and make specific analyses usable in a broader context, static analyses need to be more adaptable and require better support for variability without sacrificing performance.

A well-known approach to address variability in a managed fashion is *software product line engineering* (SPLE). We propose to design and implement static analysis frameworks as product lines in order to foster reuse of analysis components and allow for tailored but generally useful analyses.

In this paper we present OPAL, a framework for the static analysis of Java Bytecode which implements a software product line for the systematic creation of tailored static analyses. OPAL was designed to satisfy both fundamental requirements: (1) easy customizability and reusability as well as (2) performance and scalability. It uses state-of-the-art programming language abstraction from Scala to foster the development of new static analyses.

The OPAL Framework currently offers two variation points where analyses can be configured to specific requirements. First, the representation of Bytecode can be configured to the exact needs of the analysis in order to save resources and to support tools that have different requirements on the basic representation. Second, OPAL can be configured to run basic analyses in order to help higher-level static analyses by means of abstract interpretation.

The contributions of this paper are:

- An approach for designing static analysis frameworks based on software product line engineering.
- OPAL, a reference implementation for this design approach, which supports multiple representations for Java Bytecode as well as the configuration and adaptation of the performed static analyses to the needs of some user-developed higher-level static analysis.

The remainder of this paper is structured as follows. Motivating our work, we extend on related work in Section 2. In Section 3, we present a short introduction into software product line engineering. We provide a short introduction into the OPAL framework in Section 4. After that, we discuss OPAL's design w.r.t. its support for software product lines. The section ends with a discussion how it can be used to develop specifically tailored static analyses. In Section 6, we show an example where OPAL has already proven beneficial for the implementation of an analysis. We conclude the work in Section 7 with a summary and ideas for possible future work.

### 2. Related Work

In general, the idea of developing single, basic static analyses such that they are (re)usable is commonplace. But systematic reusability and composability of basic static analyses with well-/formally defined extension and variation points is not regularly addressed. An example of a step in that direction is, for example, the work on the generic framework for call graph algorithms done by Grove et al.[15]. They developed a framework that makes it possible to systematically configure the call graph construction algorithm. However, the primary purpose of that framework was to compare different call graph algorithms and not to provide a foundation for other developers of static analyses.

A second example of a framework that is related to our work is Julia developed by Fausto Spotto et al.[13]. This framework for

# A Software Product Line for Static Analyses

- Commonalities
  - we need to be able to process .class files
- Variability
  - enable different representation for .class files (e.g., if you want to write a disassembler a 1:1 representation is needed; for most static analyses a more abstract representation is required.)
  - only reify those parts that are needed

Requirement: composition based approach

**Abstract.** In general, components provide and require services and two components are bound if the first component provides a service required by the second component. However, certain variability in services – w.r.t. how and which functionality is provided or required – cannot be described using standard interface description languages. If this variability is relevant when selecting a matching component then human interaction is required to decide which components can be bound. We propose to use feature models for making this variability explicit and (re-)enabling automatic component binding. In our approach, feature models are one part of service specifications. This enables to declaratively specify which *service variant* is provided by a component. By referring to a service’s variation points, a component that requires a specific service can list the requirements on the desired variant. Using these specifications, a component environment can then determine if a binding of the components exists that satisfies all requirements. The prototypical environment Columbus demonstrates the feasibility of the approach.

## 1 Introduction

Components in a component-based system may provide and require multiple services, whereby each service is described by a service specification. A component that provides a specific service declares to do so by implementing the interface defined by the service specification. This approach of “programming against interfaces” enables low coupling and flexible designs that are malleable.

Current interface description languages (Java interfaces, WSDL interfaces, etc.) are geared towards describing commonalities between components and hiding their variabilities. However, in an open component environment, several components may co-exist that do implement the same programmatic interface, but with varying characteristics of their implementations regarding functional as well as non-functional properties. For example, it is possible that two components implementing two Payment Web Services expose exactly the same programmatic interface, but do support a different set of credit card vendors, use different security algorithms and have different levels of reliability. The description of the interface using, e.g., the Web Service Description Language (WSDL), only specifies how to interact with a web service; i.e., the data types that have to be used, the order in which the messages have to be exchanged, the transport protocol
